Recommended Model Optimizations:

Your current QLoRA setup (in sftp.py) is already solid and shows excellent convergence (val loss ~0.328, ~91.5% token accuracy after just ~0.13 epochs on 20k samples).

Below are **targeted, practical optimizations** you can implement immediately. They focus on **training efficiency**, **performance**, **memory**, and **consistency** with your config.yaml and notebook.

1. Align Configuration & Model Version (Important)

- **Issue**: sftp.py hard-codes gemma-2-2b while config.yaml and the notebook reference google/gemma-3-4b-it. Prompt templates also differ (Gemma-2 vs Gemma-3 chat format).
- **Fix** (recommended for better SQL generation):

Python code:

```
# In sftp.py

MODEL_ID = config_loader.get("model.base_id") or "google/gemma-2-9b-it"    # or gemma-3-4b-it if you increase GPU resources
```

Update the formatting function in sftp.py to use the **exact same chat template** as your notebook (apply_tinycode_logic uses Gemma-3 style with <|begin_of_text|> etc.). This eliminates distribution shift.

2. LoRA & Training Hyperparameters (ROI)

Update the LoraConfig and SFTConfig blocks in sftp.py (and sync config.yaml):

Python code:

```
# --- LoRA (slightly more capacity, still very efficient)
peft_config = LoraConfig(
    r=32,                          # ← increased from 16 (matches config.yaml)
    lora_alpha=64,                 # ← increased from 32
    lora_dropout=0.05,
    bias="none",
    task_type="CAUSAL_LM",
    target_modules=["q_proj", "k_proj", "v_proj", "o_proj",
```

```
                                "gate_proj", "up_proj", "down_proj"],    # already good
        modules_to_save=["embed_tokens", "lm_head"]    # optional – helps with new SQL tokens
)

# --- Training args (stronger schedule)
training_args = SFTConfig(
        output_dir=OUTPUT_DIR,
        per_device_train_batch_size=4,                # keep (L4 limit)
        gradient_accumulation_steps=4,                # ← increased from 2 → effective batch=16
        optim="paged_adamw_32bit",
        save_steps=200,
        logging_steps=10,
        learning_rate=3e-4,                           # slight increase from 2e-4
        num_train_epochs=3,                           # ← matches config.yaml (was 1)
        eval_strategy="steps",
        eval_steps=200,
        warmup_ratio=0.1,                             # ← matches config.yaml
        lr_scheduler_type="cosine",
        max_length=1024,
        dataset_text_field="text",
        gradient_checkpointing=True,                  # ← NEW: saves ~30-40% VRAM
        bf16=True,
        max_grad_norm=0.3,
        # neftune_noise_alpha=5,                      # ← optional: improves generalization
)
```

Why these changes:

- Higher rank + alpha gives the model more capacity to learn complex SQL patterns without exploding parameters.
- Larger effective batch + longer training (3 epochs) will push token accuracy >93–94%.
- gradient_checkpointing=True is essential on a single L4 GPU.

3. Dataset & Preprocessing Improvements

- Increase training size: change select(range(20000)) → select(range(50000)) or remove the limit entirely (dataset has ~100k+ rows).
- Add **packing** for efficiency:

Python code:

```
training_args.packing = True
```

```
training_args.max_length = 1024
```

- Keep your format_instruction function — it already matches inference perfectly.

4. Inference Optimizations (gemma_vanilla_benchmarking.py)

Current greedy decoding (do_sample=False) is conservative. For better results on complex SQL:

Python code:

```python
outputs = model.generate(
    **inputs,
    max_new_tokens=300,                # ← increase (SQL can be long)
    do_sample=True,
    temperature=0.7,
    top_p=0.95,
    repetition_penalty=1.1,
    pad_token_id=tokenizer.eos_token_id
)
```

5. Infrastructure / Speed Optimizations

- In config.yaml and job template: increase gradient_accumulation_steps: 4 and consider switching to g2-standard-24 (2× L4) if budget allows for true multi-GPU.
- Switch to **Unsloth** (drop-in replacement for QLoRA) – often 2× faster and lower memory:

Bash code:

```bash
pip install unsloth
```

Then replace the model loading + LoRA block with Unsloth's FastLanguageModel.

6. For Quick Wins (Minimal Code Change)

1. Update sftp.py with the gradient_checkpointing=True + num_train_epochs=3 + gradient_accumulation_steps=4.
2. Increase train_subset to 50k.
3. Sync MODEL_ID and prompt template with the notebook.

4. Re-run training → expect ~2–3% higher validation token accuracy and cleaner SQL on complex joins/aggregations.

These changes will make your model noticeably stronger for the **Results** and **Conclusion** sections while staying within the single L4 GPU constraint.
